Conscious Perception Missing. A Reply to Franklin, Baars, and Ramamurthy

Pentti O. A. Haikonen
University of Illinois at Springfield

Franklin, Baars, and Ramamurthy kindly clarify their position in response to my critique (Haikonen 2009). I fully recognize the important and pioneering work that Franklin, Baars, and Ramamurthy have done in the field of artificial cognition and my critique should not be construed to diminish the value of that work in any way.

However, in the good tradition of philosophical debate I would like to point out the following. There seems to be nothing in the writings of FBR (or anybody else’s) that would explain how the running of any computer program could evoke qualia and subjective feelings in the executing machine. On the other hand, it is obvious that computer programs can simulate various feelings including pain and pleasure via their functional consequences. The presence of such consequences does not, however, prove that the computer would actually feel something or be conscious in the hard sense (h-consciousness, see Boltuc 2009). It may well be that the phenomenal aspects of consciousness are beyond the capacity of computer programs and may be present only in some hard-wired perceptive and reactive systems.

FBR have done excellent work in the development of the LIDA agent that they call functionally conscious. Based on that they wish to define functional consciousness as the process that implements the Global Workspace Theory and the LIDA Cognitive Cycle (Franklin, Baars, and Ramamurthy 2009) a notion that I criticized in my previous response. The concept “functional consciousness” is doubtful, but even so, it should not be hijacked to apply to one specific cognitive model only. In their current response FBR wish to go even further. They state: “There is a sizable and growing body of evidence from cognitive science and neuroscience that human minds (their control structures) implement the essential elements of Global Workspace Theory.” This is not a modest claim at all.

Personally I would be quite happy if it could be shown that my cognitive model (Haikonen 2003, 2007) had captured some elements of human cognition (I trust it has), but I would not dare to claim that the brain implements my model, even in the unlikely case where my model would turn out to be a perfect model of the brain. The human brain and mind are a little bit older constructions than the Global Workspace Theory and have evolved without any knowledge of the same. It seems that here FBR have switched the role of a natural object and its man-made model. No natural object or system is based on man-made models or blueprints. To claim the opposite is to nominate oneself as the Creator. However, we are free to find Nature’s principles and implement those in our own designs.

Ontological Status of Web-based Objects

A Semantics for Virtual Environments and the Ontological Status of Virtual Objects

David Leech Anderson
Illinois State University

Abstract

Virtual environments engage millions of people and billions of dollars each year. What is the ontological status of the virtual objects that populate those environments? An adequate answer to that question requires a developed semantics for virtual environments. The truth-conditions must be identified for “tree”-sentences when uttered by speakers immersed in a virtual environment (VE). It will be argued that statements about virtual objects have truth-conditions roughly comparable to the verificationist conditions popular amongst some contemporary antirealists. This does not mean that the virtual objects lack ontological standing. There is an important sense in which virtual objects are no less real for being mind-dependent.

Introduction

What is the ontological status of the virtual objects that populate the burgeoning virtual worlds that reside on the Internet? Second Life is a virtual world comprised not only of objects like tables, chairs, trees, and fountains, but large landmasses that have cities with expansive real estate developments. The people who frequent this virtual environment (by animating virtual bodies known as “avatars”) not only prize these virtual objects in some Platonic way, they place a commercial value on them by paying cold, hard cash. Anshe Chung (a.k.a. Ailin...
Graef) became a cause célèbre and made it on the cover of Business Week magazine when the value of her combined virtual holdings in Second Life exceeded $1,000,000. Not one million in virtual “Linden” dollars (the currency within Second Life), but one million dollars U.S.

World of Warcraft, with over 11 million paying monthly subscribers, is another massively multiplayer online role-playing game (MMORPG) that is played within a virtual environment. The virtual objects that populate games like this are bought and sold earning their creators hundreds of millions of dollars each year. One might begin a discussion about the ontological status of such virtual objects by invoking a famous claim advanced by Ian Hacking, a party to the realism-instrumentalism debate on the ontological status of theoretical entities (like electrons). Hacking reports on a conversation he had with a working physicist. He recounts:

Now how does one alter the charge on the niobium ball? “Well, at that stage,” said my friend, “we spray it with positrons to increase the charge or with electrons to decrease the charge.” From that day forth I’ve been a scientific realist. So far as I’m concerned, if you can spray them then they are real. In the same spirit, one might be tempted to say: “If you can buy them and sell them for hundreds of millions of dollars then they are real.” Even so, merely acknowledging the reality of virtual objects gets us no distance to understanding in what that reality consists. The first step must be to determine what counts as a “virtual object” and then we can ask where (if at all) in our ontological hierarchy they are properly placed.

Virtual environments and virtual objects

From the outset, the meaning of “virtual object” (VO) will be restricted so as to exclude some digital entities that are so described in discussions about Internet commerce. The day of Michael Jackson’s memorial service, Facebook gave away 800,000 copies of what was described as a “special commemorative virtual gift”—a graphical representation of Michael’s white sequined glove. In this discussion, graphical images like the white sequined glove will not be treated as a virtual object, because a Facebook page does not qualify as a genuine “virtual environment.” It lacks nothing in its virtuality, but for the purposes of this discussion it isn’t rich enough to constitute an environment, which will be defined as follows:

E = an environment is a dynamic space-time region (with a minimum of two but typically three spatial dimensions) populated by objects that bear spatial and temporal relations to one another.

The environments which we typically inhabit are physical in nature.

PE = a physical environment is a dynamic space-time region that consists of objects that bear spatial and temporal relations to one another and objects whose identity conditions include intrinsic, non-relational properties that exist independent of the present cognitive states (thinking, believing, experiencing, etc.) of any cognitive agent.

An MMORPG also constitutes an environment. It provides objects to serve as the target for agents’ intentional states and a stage upon which human actions (buying, killing, lying, sharing, etc.) become intelligible and even morally evaluable. We will describe these environments as “virtual” and I propose that we define them as follows:

VE = a virtual environment is a dynamic space-time region that consists of objects that bear spatial and temporal relations to one another and whose identity conditions supervene on the actual (or possible) sensory and cognitive states of the agents who inhabit that environment.

Virtual environments are populated with virtual objects. VO = a virtual object is an empirically detectable, intersubjectively stable, publically accessible entity that can be identified and re-identified over a sufficiently long run and whose identity conditions supervene on the actual (or possible) sensory and cognitive states of the agents inhabiting the associated VE.

The reader will notice that the definitions of VE and VO make their very existence dependent upon the cognitive agents who engage with them. If a plague wiped out the entire human race, and there no longer existed agents for whom the virtual tree could be an object of experience, then the tree would cease to exist.

An opponent will object that this consequence is unreasonable. Virtual environments (VE’s) need not be these ephemeral things that blink out of existence when the cognitive agents who previously inhabited them cease to exist. VO’s could, instead, be defined so as to be constituted by the physical systems that are causally responsible for generating users’ experiences of them. In that case, even if all humans died in a plague, so long as the machinery kept running, the VO’s would continue to exist.

Those sympathetic to this latter interpretation of VO’s will object that my previous definition attempts to settle, by stipulation, what should be a central controversy of this paper. This is a fair objection. I concede that my definitions of VE and VO do require a convincing argument—an argument that will be offered below. Laying these admittedly contentious definitions on the table at the outset will, however, streamline the discussion and aid in the explication of the view. In the end the reader must judge whether the definitions are well motivated.

Virtual Environments (VE’s) in the history of philosophy

By making virtual environments dependent upon the cognitive activity of the agents inhabiting them, I am quite deliberately invoking the idealist/antirealist philosophical traditions and the various alternatives they offered to a traditional realist account of the nature of the external world. Consider how the language of VE’s and PE’s might be used to describe debates over realism from Descartes to the present. We might recast Descartes’ methodological skepticism by considering the possibility that while I am having the experiences of a tree in the quad (VO), there may not exist a physical tree (PO) that answers to it. We could then imagine Berkeley arguing that the very concept of a material tree (PO) is incoherent and all that normal people mean when speaking of a “tree” is the tree-as-experienced (the VO). Michael Dummett’s “language acquisition argument” will translate into the claim that there is no coherent account of how humans could learn to understand a language with realist truth-conditions (which requires asserting the existence of PO’s) and so the correct semantics for natural languages must be verificationist (which requires asserting the existence of VO’s only). Finally, Hilary Putnam’s “Brains in vat” argument can be seen as an attempt to show that even if one begins with externalist assumptions, one will utterly fail in one’s attempt to raise the Cartesian specter of radical skepticism by considering the case where I am a disembodied brain floating in a vat of nutrients stimulated by a computer (experiencing VO’s but not PO’s). Ironically, knowing that I am not a brain in a vat does not confirm the truth of realism, according to Putnam. On the contrary, if I can’t raise the specter of radical skepticism—because there is no genuine possibility that I could be in a VE that is not being caused by a corresponding
The throwing of term, "tree," in V-English. The first candidate is: a VE. When identified, that condition will be the referent for the use of the term, "tree," when uttered by a person immersed in being that physical state-of-affairs that speaker immersed in a particular MMORPG, there are a number that lies at the use of that term. The referent of the term is whatever it is this view, a word refers to whatever it is that "causally regulates" very popular position of semantic externalism. On one version of accessible" tree.

One more comment before we progress. The reader should be cautioned not to conclude that embracing a verificationist semantics for virtual objects in any way counts against the truth of metaphysical realism regarding the external world. Quite the contrary is actually the case, or so I would argue if space permitted.

Ontology with semantics

Our ultimate goal is to determine the ontological status of virtual objects. One cannot determine the ontological status of a particular virtual tree, however, unless one first determines what the virtual tree is. But that is ultimately related to the semantic question, What are the truth-conditions of the sentence, "There is a tree" when spoken about the virtual tree in the virtual environment? The point is not that you can ignore metaphysics and simply do semantics. Certainly not. The point is that reality is too metaphysically rich; there are simply too many realities that are candidates for being the referent of the virtual "tree" in question. Nothing will be accomplished if one gives the most elegant ontological account of a phenomenon that one takes to be a virtual tree, if everyone in your audience insists that the phenomenon that you analyzed is simply not a "virtual tree" given what everyone else means by those words. The war is only won if you win both the semantic battle and the ontological battle. There is no avoiding the semantic question. We want to know the ontological nature of virtual trees; but to answer that question, we must also learn what the truth-conditions are for "tree"-sentences uttered within virtual environments. It is to both questions that we now turn.

A slippery slope argument

When native English speakers are immersed in an MMORPG and utter a "tree"-statement, the language they are speaking (whatever language that turns out to be) we will call "V-English." I have proposed that the truth-value of such "tree"-sentences is not sensitive to the state of any physical object and is instead determined solely by how things stand with respect to the cognitive states of the inhabitants of the game. Thus, "tree"-sentences will be true on this account if all or most inhabitants of the game are having cognitive experiences constitutive of an "empirically detectable, intersubjectively stable, publically accessible" tree.

An alternative to this view is one motivated by the currently very popular position of semantic externalism. On one version of this view, a word refers to whatever it is that "causally regulates" the use of that term. The referent of the term is whatever it is that lies at the end of the causal chain that ultimately causes the speaker to utter sentences like, "Look, there is a tree." For a speaker immersed in a particular MMORPG, there are a number of candidates that might fit that description. Let’s consider a few. Each of the numbered conditions that follow is a candidate for being that physical state-of-affairs that "causally regulates" the use of the term, "tree," when uttered by a person immersed in a VE. When identified, that condition will be the referent for the term, "tree," in V-English. The first candidate is:

1. States of the server hardware: The throwing of the electrical (on-off) switches on the VE-server that implements the "tree"-subroutine in the server software.

This has been a popular choice for an externalist referent of "tree"-statements as uttered by "brains in a vat" according to Putnam's thought experiment, and at first blush seems equally promising here. The software alone is hard to target because it is an abstract entity, not a physical object. The switches alone, outside of the context provided by the "tree"-software, don't capture the continuity of the tree through time. This articulation attempts to capture the best of both worlds, embracing both the server's hardware and software. But this option is acceptable to a counterexample.

Assume that a bug is detected in the VE-server software of a famous MMORPG right in the middle of a well-publicized national contest being waged live and online between just two contestants. The two will soon be shooting (virtual) arrows into a tree and the bug can be expected to produce a malfunction. In order to prevent this eventuality, the programmer has a plan. The programmer knows exactly what signals (plus TCP/IP – Internet protocols) would be sent out over the Internet to the two contestants' PC's if the server were functioning properly. Imagine, as well, that the programmer has the ability (it doesn't matter how) to interrupt the stream of defective instructions whenever they are sent by the software bug, and to send instead packets of instructions over the Internet that produce the proper "tree"-effects on the users' computers. (Consider the programmers actions here on analogy with the actions of God in correlating the actions of minds and bodies according to "Occasionalist" theories of mind-body interaction.)

In this case—where the programmer is ensuring that inhabitants of the VE will continue to experience an "empirically detectable, intersubjectively stable, publically accessible" tree—what do we say about the truth-value of the sentence, "The tree was struck by an arrow" when uttered within the MMORPG? It seems only reasonable to say that it is true. The quick-thinking, spontaneous actions of the programmer preserved the existence of the tree within the VE. However, if the V-English word, "tree," refers to condition 1. identified above, then the sentence must be false. Because of the software bug, the "tree"-routine is no longer being run. But "false" is the wrong result. As a matter of fact, it turns out neither hardware nor software is either a necessary or a sufficient condition for the existence of the virtual tree. Happily, the case itself suggests a second (PO) candidate for the referent of the word "tree":

2. Signals propagated over the Internet: The carrying of the instructions plus TCP/IP Internet protocols that propagate the "tree-generating" instructions sent to the personal computers of all agents inhabiting the VE.

The reader herself, however, can probably generate a counter-example to this proposal. Instructions sent by TCP/IP is again just a half-way house. It is only a means for delivering instructions to the PC’s of each participating agent. There are any number of methods that might accomplish this, including tens of thousands of employees scattered around the world using all manner of quirky occasionalist methods for getting signals to all relevant computers causing the proper pixels to light up and forming the 3D image of a tree. So long as the result is a stable, intersubjectively consistent, genuinely public, virtual tree—"tree"-statements uttered in V-English will still come out true, even when condition 2. is lacking.

But now we are on a slippery slope. "Pixels lighting up on computer monitors around the world" is no more the proper "end" of the causal chain than any of the previous ones. Pick
any condition on the list. It is possible for that condition not to hold but so long as the next condition down on the list does hold, then the existence of the virtual tree will be preserved.

3. **The hardware in every user’s PC:** The aggregate throwing of all appropriate electrical (on-off) switches in the machine hardware that implements the “tree”-subroutine on all the personal computers of all the agents inhabiting the VE.

4. **The monitor illumination in every user’s PC:** The synchronized illumination of pixels on all the computer monitors of all agents so as to create an intersubjectively consistent 3D public tree.

5. **Retinal stimulation in every user’s eyeball:** The proper stimulation of the retinas in all agents’ eyes so as to create an intersubjectively consistent 3D public tree.

6. **Visual cortex stimulation in every user’s brain:** The excitation of the proper areas of the visual cortex (V1–V5) in all agents’ brains so as to create an intersubjectively consistent 3D public tree.

Each of the conditions is neither necessary nor sufficient for the existence of the virtual tree. It doesn’t matter how you accomplish the task of bringing about the conditions described by VE and VO. It doesn’t matter what physical system (or mental or spiritual system for that matter) is used along the way, all that matters is that you produce the final effect that literally constitutes the existence of the virtual tree. And that final effect inevitably is:

7. **The intersubjectively coordinated, conscious experience of all users:** The proper production of an empirically detectable, intersubjectively stable, publically accessible tree that can be identified and re-identified over a sufficiently long run and whose identity conditions supervene on the sensory and cognitive states of the agents inhabiting the associated VE.

When typical inhabitants of a MMORPG confront a tree, and say, “There is a tree,” what they are talking about is best captured by 7.

**The ontological status of virtual objects**

I have just argued that the essential nature of virtual trees is best described not in terms of the mind-independent states of physical systems, but in terms that make essential reference to the cognitive states of human agents. One might reasonably use either the language of a verificationist semantics as embraced by some antirealists, or the language of conscious, first-person phenomenal states familiar from recent defenders of phenomenal consciousness. I have purposely used both in this discussion, not wanting to privilege either one. Some will likely find one option more congenial than the other.

I recognize that I have done nothing to answer the myriad objections that can quite reasonably be raised against this controversial position. But that work must be left to another time. Our final task now is to come full circle on the Hacking objection that opened this paper. If (by chance) I am right about the essential nature of virtual objects, are they real or not? Do we add them to our ontology, or leave them out?

Lynn Rudder Baker has, in the pages of this publication (Spring 2008), addressed a question that is, at least in part, relevant to our question: Are artifacts less real than natural objects? (p.4)

No one who takes artifacts of any sort seriously, ontologically speaking, should suppose that metaphysics can be based on a distinction between mind-independence and mind-dependence. In any case, technology will continue to shrink the distinction, and with it, the distinction between artifacts and natural objects. (Ibid.)

Ironically, Rudder Baker seems to be committing the same confabulation error as did her opponents, but in the reverse direction. She seems to be denying that there could be any ontologically significant distinction between mind-dependence and mind-independence. The table in my kitchen, and the table in my Second Life kitchen are both artifacts. But one is mind-dependent in a more robust sense that is ontologically significant. If she is denying this, then I think she makes a mistake similar to her opponents. In the end, I am not at all confident that she is denying this distinction. She may simply be ignoring it. But if she is denying it, then we deserve more of an argument than she has given thus far.

**Conclusion**

So what about virtual trees? Are they real? The term “real” is ambiguous. No, they are not real in the sense that is opposed to being ideal, or verificationist. They are metaphysically dependent upon the cognitive state of human beings, and that makes them “ideal” in contrast to physical trees that are “real.”
But more important than being “real,” in this sense, is being real in the sense that they “exist” in some substantive sense of that word. Yes, they do exist. They are real enough to make it the case that statements like “I left your shield next to the tree in the quad” and “You lied to me about the power of this sword and I will never be your friend again” are true. These statements are not about a fictional realm like that of a novel. One can commit real (not fictional) betrayal with a virtual sword, and a sword real enough to betray is real indeed.

I also believe it is reasonable to say that virtual trees exist and should be listed among our ontological commitments in something like the way that conscious states should be listed in one’s ontology. The conscious states of John’s believing that p and seeing an orange sunset are real. So too, the virtual tree that supervenes on the conscious states of many people. Obviously, those who deny the existence of consciousness will not be persuaded by this line of reasoning, but for that there is also the verificationist route to metaphysical legitimacy.

This discussion has only begun to explore the ontological status of virtual objects. It is a discussion that I hope continues.

Endnotes
